Visualization of the cardiac excitation and PVC arrhythmia on a 3D heart model

Pranav Sreedharan Veliyara

A Thesis Submitted to the Graduate Faculty of

GRAND VALLEY STATE UNIVERSITY

In

Partial Fulfillment of the Requirements

For the Degree of

Master of Science in Engineering

School of Engineering

August 2017

Acknowledgements

I would like to thank first my thesis advisor Dr. Samhita Rhodes for her continuous guidance and support throughout my studies at Grand Valley State University (GVSU). She has been a wonderful thesis advisor.

I would also like to thank my thesis committee members Dr. Robert Bossemeyer and Dr. Nicholas Baine for their valuable inputs for this thesis. Their participation helped me to conduct my research successfully.

I would like to thank Mr. Eric VanMiddendorp, former student at GVSU for providing necessary reference documents and research materials to start my thesis. I would also like to thank Mr. Deepak Dileepkumar, former student at GVSU for helping me with the implementation of the Graphical User Interface design in MATLAB.

I would like to thank all the staff and faculty of GVSU who directly or indirectly helped me to conduct my research.

Finally, I would like to thank my parents, family and friends for their continuous support and encouragement.

Pranav Sreedharan Veliyara

Abstract

Visualization of the cardiac potential movement is important in understanding the physiology of the human heart. A 3D visualization tool will help the cardiology students and others interested in human physiology to understand the functioning of the heart. In this thesis, such a tool is proposed which helps in the visualization of the cardiac potential movement and Premature Ventricular Contraction (PVC) event on a 3D heart model. The cardiac excitation obtained from a limb lead and a precordial lead of a 12 lead electrocardiograph (ECG) is mapped on a 3D heart model with fixed conduction pathways. The 3D heart model is obtained by modifying an existing anatomically accurate heart model. Fixed conduction pathways are defined on this derived 3D heart model. Each component of the ECG corresponds to the potential movement along each segment of these conduction pathways. The timing information from the limb lead signal is used to map the position of the cardiac potential on these conduction pathways. Amplitude and the timing information obtained from the precordial lead is mapped on a vector which points towards the corresponding precordial electrode on a separate window. This helps in understanding the instantaneous position of the cardiac potential on the transverse plane. Mapping of the cardiac excitation on the conduction pathways will stop and the color map of the heart will change during the occurrence of a PVC event. MIT-BIH arrhythmia database signals with at least one PVC wave were considered as input signal. It is observed that the system was able to detect PVC approximately 95% of the time (for the selected sample signals) and was able to map each ECG component accurately on the conduction pathways with minimum mapping delay.

1. Introduction

One of the most complex organs in the human body is the heart. The heart, along with other components in the circulatory system - arteries, veins, lymph vessels and lymph nodes coordinate blood circulation. Cardiac potentials generated by the myocardial cells result in the cardiac contraction and the circulation of blood through the rest of the body. Each normal heart beat is the result of an action potential, originating in the sinus node, which spreads through the atrial and ventricular muscle cells resulting in a coordinated pumping action. This spread of excitation can be recorded on the surface of the body by an electrocardiogram (ECG). Abnormalities in this cardiac potential generation or disruptions in cardiac conduction can cause arrhythmias and complications in the circulation of oxygen and nutrients to the brain and body.

Difficulties in determining cardiac pathology and the complexity of the heart structure itself makes ECG signal processing a very valuable focus of research. Some of the cardiac signal processing studies involve arrhythmia analysis, wireless pacemaker design, and cardiac function irregularity studies, to name a few. Various physical and software tools are available to make the task of visualizing heart function easier for cardiologists in training. These tools can also be used by cardiac surgeons to explain procedures to patients and caregivers unfamiliar with cardiac anatomy and function.

A majority of the software tools are not readily available to the lay population and can be expensive. One of the few freeware tools available online is 'ECGSIM', a simulation tool developed by the scientists at Radboud University Medical Center, Netherlands. ECGSIM is a visualization tool which displays cardiac potential spread as a field movement on the surface of a 3D heart model. It has a definite set of input signals and a unique 3D heart model. ECGSIM can also demonstrate electrical characteristics, and simultaneously display

the spread of the potential over the thorax. However, this model does not provide any information about possible conduction pathways. Input signals are not continuous and just limited to a single heartbeat. In addition, arrhythmias are not modeled in ECGSIM.

The primary objective of this project is to develop a 3D ECG visualization educational tool for medical students undergoing cardiology training, and patients wanting to learn about cardiac procedures. This thesis represents the second phase of that bigger project [1]. In this thesis, a novel heart visualization tool is proposed which is an interactive MATLAB based tool that can visualize a continuous ECG signal with cardiac conduction pathways. A premature ventricular contraction (PVC) arrhythmia detection module is also part of the proposed system. Other modules are the QRS detection and 3D mapping modules. ECG signals from the MIT-BIH arrhythmia database are used as input signals. This system also helps the user to visualize the relation of the potential movement with the corresponding precordial lead vector. The PVC detection algorithm developed for this thesis uses multiple thresholds in a unique combination to determine whether a given R_{peak} is a PVC peak or not. There are two levels in this thresholding hierarchy. Screening using the first threshold which is an average R_{peak} to R_{peak} interval is performed in the first level. Data that qualifies this threshold is further screened in the second level using the other two thresholds. If the screened data qualifies either of these thresholds in the second level, it is identified as a PVC peak. The first threshold searches for large R_{peak} to R_{peak} intervals, the second threshold finds abnormally large R_{peaks} and the third threshold finds the negative peaks.

2. Literature Review

2.1. Background

2.1.1. Physiology of cardiac excitation

The human heart is four chambered with two thin walled upper chambers called the atria and two thicker walled lower chambers called the ventricles. The right atrium and the right ventricle is involved in the pulmonary circulation by sending deoxygenated blood arriving from the different organs to the lungs for oxygenation. The left atrium and ventricle is responsible for systemic circulation by receiving oxygenated blood from the lungs and distributing to the rest of the body. Thus, the two circulatory components are completely isolated from one another. This prevents the oxygenated and the deoxygenated blood from mixing. Figure 1 shows the anatomy of the mammalian heart.

Figure 1 Heart anatomy [2]

The heart wall is made up of cardiac muscles, composed of strong muscle fibers which is unique compared to the other muscle fibers in the body. Certain groups of smaller muscle cells do not contribute to the pumping action due to their weak contractile feature. The SA node is one such group of cells. It acts as the pacemaker of the heart. These cells rhythmically produce action potentials which spread via gap junctions to the fibers of both atria. Gap junctions are the intercellular connections which transports nutrients and electrical signals. This potential flow results in the atrial contraction and subsequent ventricular contraction rhythmically, which causes a heartbeat. The action potential which is generated from the SA node reaches the atrioventricular (AV) node at the junction between atria and ventricles, and then moves rapidly through the bundle of His and Purkinje fibers to excite both ventricles, which then contract. This synchronous electrical activity is necessary for the mechanical contraction of the heart. These recorded signals are popularly known as an electrocardiograph (ECG), which is the electrical activity of the heart with respect to the ground electrode. Figure 2 is a Wigger's diagram which shows the relation of the cardiac activities with an ECG segment.

Figure 2 Wigger's diagram [3]

An ideal ECG wave with peaks labelled, can be observed in the Wigger's diagram. ECG is composed of three phases: atrial depolarization, ventricular depolarization, and ventricular repolarization in preparation for the next beat. P-wave is produced by the atrial depolarization. QRS complex is produced by the ventricular depolarization and the atrial repolarization. Signal strength of the atrial repolarization is negligible compared to the ventricular depolarization. T-wave is produced by the ventricular repolarization.

2.1.1.1. Conduction pathway

The electric potentials generated from the SA node travel along well-defined paths to complete one cardiac cycle. As mentioned earlier, the first segment of this path connects the

SA node and the AV node. Then the potential is delayed for approximately a tenth of a second in the AV node and then moves to the bundle of His and Purkinje fiber.

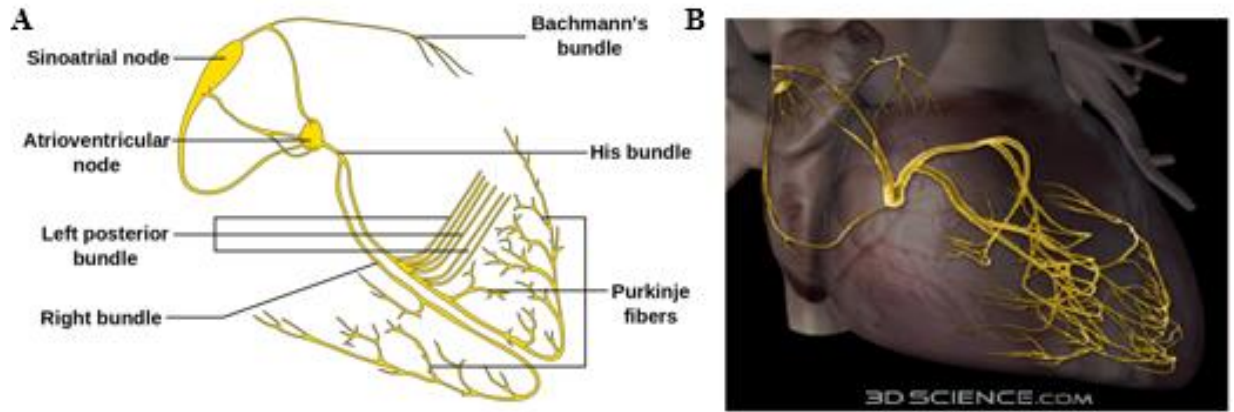

Figure 3 (A) 2D representation of conduction pathway with labels [4], (B) 3D model of the human heart and the conduction pathway [5]

Components of the conduction pathways shown in the Figure 3 are as follows:

- SA node – Sino Atrial node is the natural pacemaker of the human heart. This node is located in the myocardium just internal to the epicardium situated on the inner wall of the right atrium, where superior vena cava enters the chamber. An action potential generated in the SA node, spreads from cell to cell starting in the right atrium. Simultaneously, the Bachmann's bundle conducts the potential to the left atrium. Paths that the cardiac potential is spread throughout the right atrium are known as the internodal pathways, after which the potential reaches the AV node.
- Internodal pathways – Paths which connect the SA node to the AV node are known as internodal pathways. There are three internodal pathways: posterior or Thorel's tract, middle or Wenckebach's tract, and anterior internodal tract. The anterior internodal path projects a branch to the left atrium which is known as Bachmann's bundle.

- AV node – The Atrio Ventricular node is located at the lower side of the interatrial septum near the coronary sinus opening. Cardiac potential delays at the AV node for a fraction of a second. Atria pumps blood into the ventricle during this delay. Only after this delay do the ventricles contract. Hence, AV node and this delay is critical in maintaining the pace of the cardiac cycle. Prolonged delay or atrial depolarization's inability to reach the AV node are the most common abnormalities which can cause several arrhythmias.
- Bundle of His – The bundle of His is located at the inferior side of the interatrial septum. It helps to transmit the cardiac potential impulse from the AV node to the ventricles. As shown in Figure 3, the conduction pathway divides into two branches from the bundle of His. One path towards the left ventricle and the other path towards the right ventricle through interventricular septum. The left branch further divides into left anterior and left posterior fascicles.
- Purkinje fiber – Purkinje fibers are the last segment of the conduction pathways. Purkinje fibers extend from the bundle of His and then spread along both ventricle walls. QRS segment in the ECG signal is a result of the spread of cardiac potentials from the bundle of His to the Purkinje fibers and through the ventricular cardiac muscle. Impulse firing rate of the Purkinje fibers is 15 to 40 beats per minute. Abnormal cardiac potential generated from the Purkinje fibers are known as Premature Ventricular Contractions (PVC). PVCs are one of the most common arrhythmias.

2.1.2. Electrocardiogram

The cardiac excitation is recorded in various different ways: three lead ECG system, twelve lead ECG system, vector cardiogram (VCG), and phonocardiogram are some of these techniques. Twelve lead ECG system is the most popular one. This ECG system records

information of the electrical activity from all three orthogonal planes using its unique lead placement. ECG data for normal sinus rhythm from a standard 12 lead recording system is shown in the Figure 4. Simultaneously obtained data from the two leads of the standard 12 lead system (MIT-BIH arrhythmia database) is used as input signal in this thesis. Lead II (only available limb lead data in the MIT-BIH arrhythmia database) is used as the channel 1 input and any available precordial lead is used as the channel 2 input.

Figure 4 Twelve lead ECG [6] [21]

2.1.2.1. Lead placements

The 12 lead ECG system is composed of two groups of leads, each consisting of 6 leads. 6 limb leads and 6 precordial leads (or generally known as chest leads). The limb leads are bipolar and precordial leads are unipolar. Three of the 6 limb leads are augmented leads. Figure 5 shows the lead vectors of a standard 12 lead ECG system. Electrode placement on the subject's body is as listed in the Table 1. Combination of the potentials at these electrodes are used to derive lead vectors.

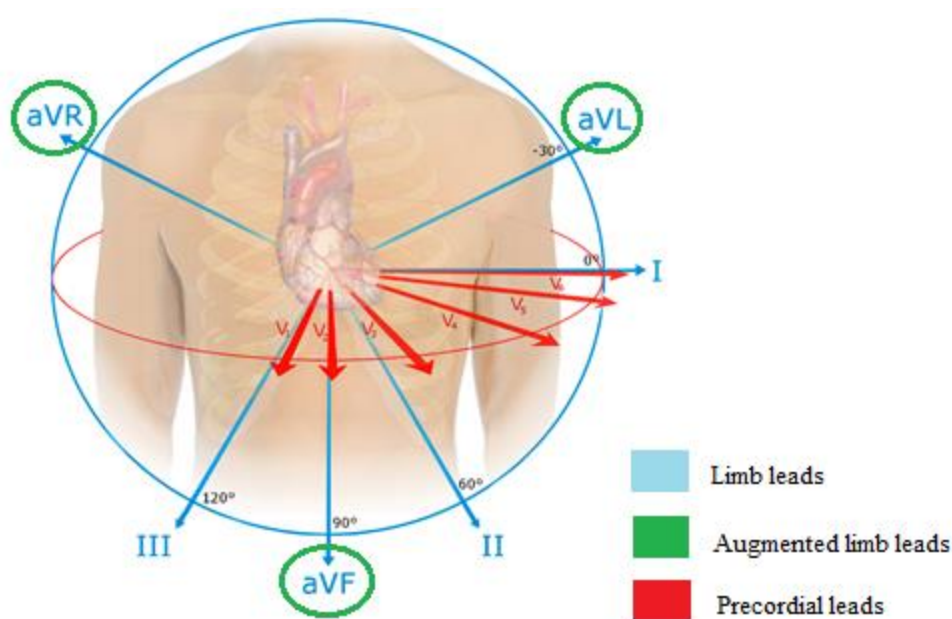

Figure 5 Lead placement - 12 lead ECG [7]

Table 1 Twelve lead ECG electrode placement on the human body

Electrode	Electrode placement
Right Arm (RA)	Near inner side of the right hand wrist
Left Arm (LA)	Near inner side of the left hand wrist
Right Leg (RL)	On the right leg lateral calf muscle.

Left Leg (LL)	On the left leg lateral calf muscle.
V ₁	Between 4th and 5th ribs, near the right side of the sternum
V ₂	Between 4th and 5th ribs, near the left side of the sternum
V ₃	Between leads V ₂ and V ₄ .
V ₄	Between 5th and 6th ribs, near mid-clavicular line
V ₅	Horizontal with V ₄ , on the left anterior axillary line.
V ₆	Horizontal with V ₄ and V ₅ , on the mid-axillary line.

2.1.2.2. Limb leads

The limb lead potentials are measured using the electrode potential differences as follows.

$$\text{Lead I: } \quad VI = LA - RA \quad (2.1.2.2.1)$$

$$\text{Lead II: } \quad VII = LL - RA \quad (2.1.2.2.2)$$

$$\text{Lead III: } \quad VIII = LL - LA \quad (2.1.2.2.3)$$

Since two electrodes are required to derive one lead potential, these leads are known as bipolar leads. According to Einthoven's lead system, it is assumed that the heart is located at the center of a homogeneous sphere representing the torso [8]. RA, LA, and LL leads are positioned at the vertices of an equilateral triangle inside this sphere, with the heart located at its center. Three vectors are formed connecting two electrodes at a time. They are lead I, II and III vectors. Vector sum of the two of these leads results in the third lead's potential. This is stated by Einthoven's law and the equilateral triangle is known as Einthoven's triangle. Vector sum of the three leads are mapped on the Einthoven's triangle.

Figure 6 and Figure 7 shows the relation between the potential movement and the cardiac vector. At a given time, position of the cardiac potential on the heart and the corresponding lead vector potential on Einthoven's triangle can be observed from these figures. The red

colored region on the heart shows the potential spread and the blue region is the remaining portion of the heart. The yellow vector inside the Einthoven's triangle is the resultant cardiac vector. Path traced by this vector's head is shown in green color. Vector components along each side of the triangle gives the individual limb lead potential. Corresponding potential is mapped as ECG. The cardiac potential's movement from atria to ventricle and the generation of P, Q and R_{peaks} can be observed from Figure 6. Remaining ECG components and corresponding cardiac potential can be observed from Figure 7.

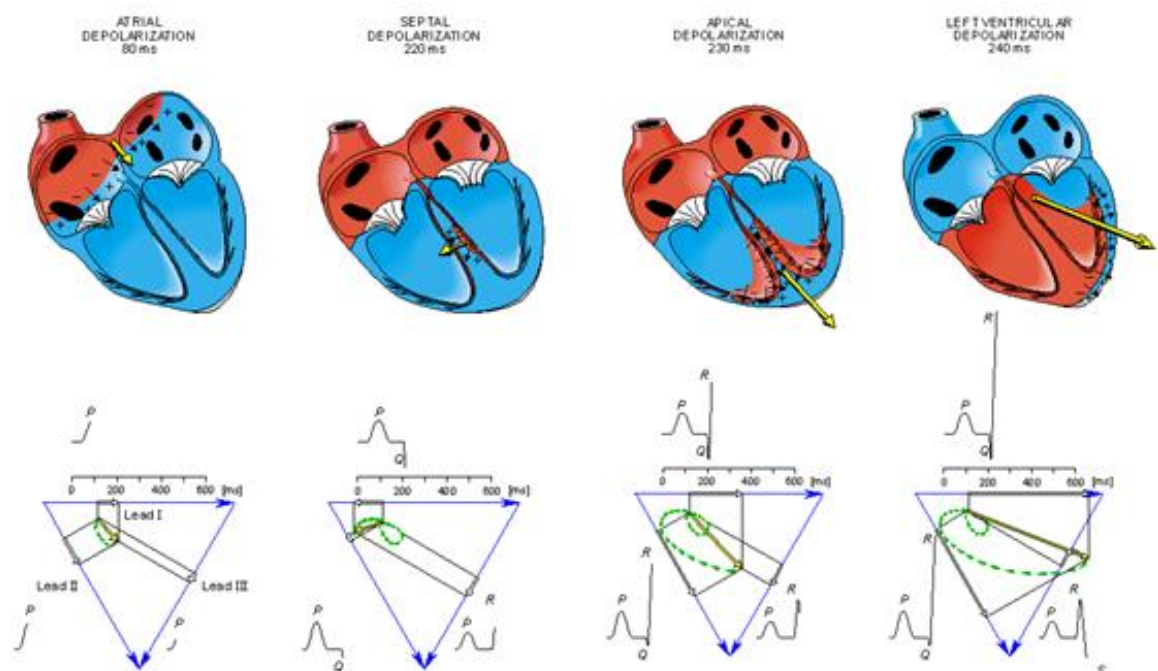

Figure 6 Lead vector motion with respect to ECG segments (P and Q) [8]

Figure 7 Lead vector motion with respect to ECG segments (QRS and T) [8]

2.1.2.3. Augmented limb leads

Augmented limb leads are pointed in different directions compared to the limb leads. These lead vectors are pointed towards the vertices of the Einthoven's triangle from the center region. Augmented lead vectors are derived using Goldberg's central limit theorem which is the sum of the three limb electrodes in a unique combination. Augmented limb leads are not used as input signals in this thesis.

2.1.2.4. Precordial leads

This is a set of 6 electrodes placed on the left side of the chest, near the heart along the transverse plane. These leads are unipolar vector and originates at a common lead or commonly known as Wilson's central terminal. The Wilson's central terminal is obtained by averaging the potential at the limbs with reference to the electrode on the right leg using three

identical resistors ($\geq 5 \text{ k}\Omega$) connected to a single point. This terminal is assumed as negatively charged and the precordial leads are positively charged. Wilson's central limit theorem,

$$V_W = \frac{1}{3}(RA + LA + LL) \quad (2.1.2.4.1)$$

Where,

V_W = Wilson's central terminal

Each lead is placed 30° apart from the previous lead. See Figure 8 to understand the direction of the leads (V_1 to V_6) in the transverse plane.

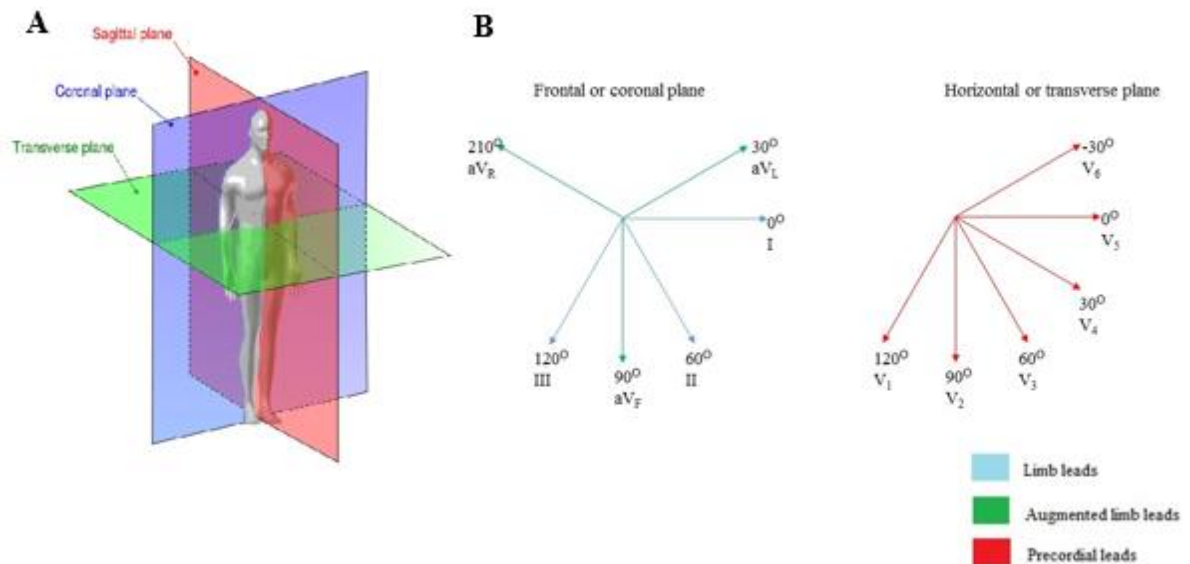

Figure 8 (A) Planes with respect to the human body [9] and (B) the lead placement angles

2.2. Visualization of the human heart

Research in cardiology ranges from electronic health record systems to artificial invasive pacemakers (refer Appendix III for related reference documents). These studies include visualization as well. The primary objective of this thesis is to visualize heart activity on a 3D

space. The following sub sections discuss current research on 2D and 3D visualizations of the human heart. The visualization of normal sinus rhythm and PVC arrhythmia are proposed and implemented as part of this thesis.

2.2.1. 2-Dimensional heart models

Sovilj's heart model [10] is a 2D heart model where all the conduction pathway components are labelled. This is a bi-domain finite element heart model which uses color variation to represent the movement of the electric potential through the walls. This model was developed using COMSOL Microphysics, a finite element analysis software. A 2D model with a very high anatomical accuracy was developed in this research. Volume conductor effects of blood, tissues, and torso were accurately matched to develop the 2D heart model using COMSOL features. Constraints such as conductivity of the heart tissues and blood tissues can be adjusted using COMSOL. Modified FitzHugh-Nagumo [10] method was used in this model to simulate the various electrical activities.

Second model is Balakrishnan's model [11], a simplified 2D model which shows the potential spread on a 2D image of the conduction pathway. This model is essentially a cell network. Individual cells changes state based on the position of the electric potential. Each state is represented by a different color. Each cell is connected to the neighboring 8 cells. A gap junction is present between the cells. Conductance of this junction is varied based on the properties of the tissue which the cell represents. When potential conducts from one cell to another, the state of the previously excited cells and current cell are changed to different colors. Electrical activity mapping and 2D network is developed using reduced FitzHugh - Nagumo model [11] and Aleiv – Panfilov model [11].

2.2.2. 3-Dimensional heart models

A 3D heart model was developed in Malchenko's research [12] [20]. In this model, an envelope of the human heart was reconstructed from the MRI images using MATLAB. Coordinates from 10 time moments were recorded for this reconstruction. Each time moment consists of 16 images of the heart. A contour is sketched connecting the coordinates obtained from each image. Collection of these contours corresponding to each time moment were used to draw splines across the heart surface. A 3D heart envelope is obtained from these contours and vertical splines. Figure 9 shows the contours and the resultant 3D structure of the heart. Internal properties of the heart including the position and dimension of the chambers, walls, septum, and valves are not considered in this design. This heart model is used for several other research [13] [14] to study the heart's functionality during various arrhythmias. Due to its unique structure that is anatomically correct and since it is available as open source, Malchenko's 3D model is used to build the simulation tool discussed in this thesis.

Figure 9 Malchenko's. Contours (left), 3D heart surface (right) [12]

Second 3D model is ECGSIM [15], a simulation software which helps the user to study the relation between ECG and cardiac potential flow on the surface of the heart. This software can display input signal as 12 lead ECG, VCG, body surface map (BSM), minimap montage (using 9 electrodes), and single lead ECG. The corresponding potential spread is displayed on

the surface of a unique 3D heart surface as shown in Figure 10 which is the output window of ECGSIM.

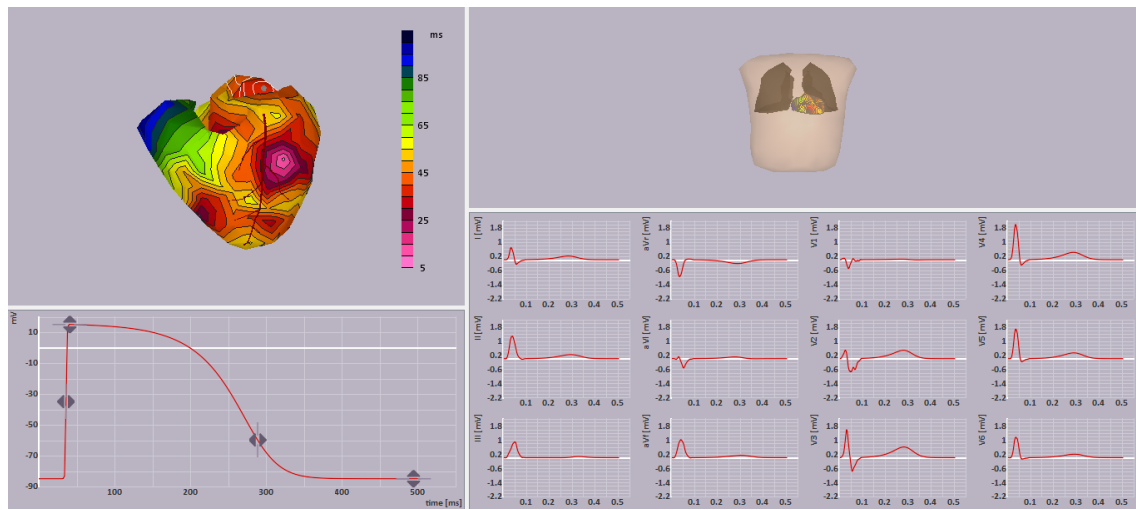

Figure 10 Output window of ECGSIM for a 12 lead input ECG signal

In Figure 10, the 3D heart model can be observed in the top left corner. The torso can be seen on the top right corner. The position of the heart inside the torso can also be observed. The bottom left graph is the transmembrane potential of a selected node. The bottom right window is the input signal display window. The 3D model allows the user to select single or multiple nodes on the heart surface to set constraints like amplitude parameters or slope parameters of transmembrane potential. Corresponding changes can be visualized on the ECG display window. Potential spread on the 3D heart will not change based on this selection. Color mapping represents the time (in ms) at which activation wave front reaches each region. Even though ECGSIM is a complete simulation package, it has some major limitations. ECGSIM cannot accept external input signals. User does not have freedom to input a recorded ECG signal or a real time ECG signal to the system to visualize its properties. In addition, ECGSIM does not give any information about any kind of arrhythmia.

Third 3D model is ‘the living heart project’ [16], a 3D heart model developed by Dassault Systems. This model is built on Simulia, a simulation suite of Dassault Systems. It can display activities of a human heart in a realistic way. Virtual reality experience is the unique feature of this model. It helps in better visualization of the heart diseases as well. Physician can visualize the abnormality in the functioning of the heart using the virtual reality feature and propose suitable surgery or medication. PVC event visualization implemented in this thesis is inspired from this system.

2.3. PVC arrhythmia

Premature Ventricular Contractions have some unique properties compared to the normal sinus beat. Longer QRS duration and larger peaks of the PVC make it easy to detect manually. Fluttering, pounding, skipped beats etc. are some of the most common symptoms of PVC. During a PVC, ventricles contracts before atrial depolarization completes.

Even though PVCs do not occur often in a given time interval, certain types of PVCs occur at regular intervals. As the name suggests, the bigeminy PVC occur in every other beat, the trigemini in every third beat, and the quadrageminy in every fourth beat. Paired PVC has a unique feature of two abnormal peaks every occurrence. There are more varieties of PVCs. A common feature is the uniqueness in the time interval and amplitude compared to a normal beat. Some of the most common algorithms used to detect PVCs are template matching algorithm [17], Bayesian detection [18], and wavelet-transform based algorithms [19].

Even though PVC on a healthy patient is no reason for concern, PVC coupled with other health conditions can be associated with various diseases. For example, recent studies shows that the frequent PVCs may result in causing heart failure in patients with dysfunctional left ventricle [23]. PVC can be dangerous to the patients suffering from coronary artery disease or valve disease. Thus it is important to detect and track the frequency and amplitude of PVCs.

3. Specific Aims

In this thesis, following steps were conducted to develop a 3D visualization model of the cardiac activity.

- Develop or obtain an anatomically accurate MATLAB readable digital 3D heart model.
- Define conduction pathways using this 3D heart model.
- Obtain cardiac excitation signal and remove noise.
- Obtain the timing information corresponding to each cardiac activity using this signal.
- Map the cardiac excitation signal on the respective 3D space of the heart model based on the timing information.
- Implement PVC arrhythmia detection module using a suitable peak detection algorithm.
- Test the efficiency of the system using accuracy test and running time test.
- Evaluate the specificity and sensitivity of the PVC detection algorithm.
- The expected end product is a GUI based software which can be used as an educational tool.

4. Methodology

This section describes the algorithms used to implement the proposed ECG visualization tool. All five modules are implemented using MATLAB 2015. MIT BIH arrhythmia database signals are used as input signals. This database is a collection of 30 minutes long 48 recordings performed on 47 subjects. It consists of 2 channels. In majority of the recordings, first channel consists of a limb lead signal (lead II in most of the signals) and the second channel consists of a precordial signal. The lead II and a precordial lead signal sampled at 360Hz frequency are the available information for most of the recordings in this database. So, these orthogonal leads are used in this thesis for visualizing the heart activity. Figure 11 is the functional block diagram of the proposed system. Main features of the system are as follows:

- An interactive MATLAB based GUI.
- Anatomically accurate 3D heart envelope.
- 3D visualization of the conduction pathway.
- Visualization of the movement of cardiac visualization using ECG segment timing information.
- Robust PVC arrhythmia detection algorithm.
- Morbidity warning system.

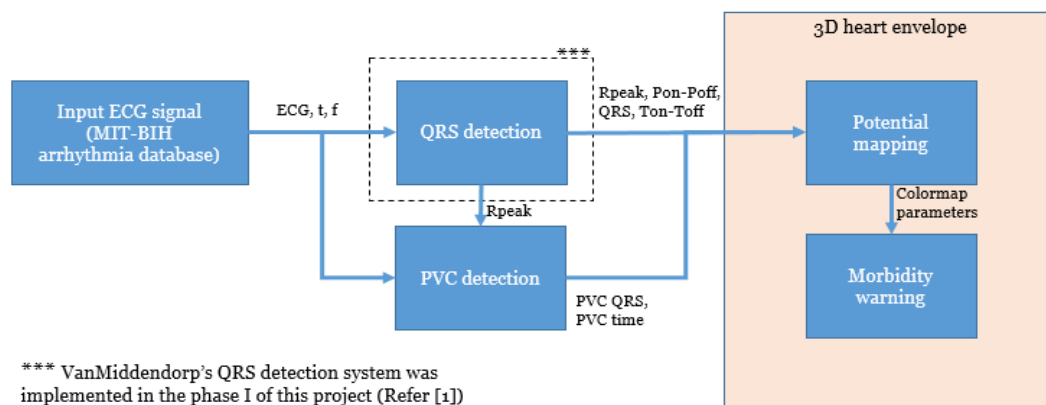

Figure 11 Proposed 3D heart visualization system

4.1. QRS detection module

This module was implemented in the first phase of this project in a Grand Valley State University master's project titled 'Electrocardiogram Delineation Method Using Wavelet Transform and Novel Display Method [1]'. This is a wavelet transform based ECG feature extraction module implemented in MATLAB using delineation algorithm. 'Symlet' wavelet transform is used to decompose the raw signal into 8 levels, each representing different frequency ranges. Frequency components corresponding to low frequency noise are subtracted from the original signal and the high frequency noise is eliminated using a soft thresholding method. A set of adaptive windowing and adaptive thresholding is used to extract fiducial points from this denoised signal. These fiducial points are mapped on the original signal and displayed as output waveform. The algorithm is detailed in Appendix II. Figure 12 is a sample output obtained from this module after processing a raw ECG signal. Fiducial points R_{peak} , QRS_{on} , QRS_{off} , P_{peak} , P_{on} , P_{off} , T_{peak} , and T_{end} are exported to the potential mapping module to obtain the timing information.

Figure 12 ECG delineation in MIT-BIH ECG signal - 105

4.2. PVC detection module

Wider R_{peak} to R_{peak} intervals (RRI) compared to the mean RRI, early occurrence of the QRS complex and larger peak amplitudes compared to the normal ECG waves are the common characteristics of PVCs. As mentioned earlier, PVCs can occur at regular intervals, but not always. The frequency of PVCs possibly suggest a health condition of the subject. Following flowchart (Figure 13) demonstrates the PVC detection algorithm developed for this thesis.

Figure 13 PVC detection algorithm flowchart

This algorithm is adapted from the Chang's model [19] with a modification in the combination of the threshold usage. The PVC peaks are detected using three different thresholds in both algorithms. However, unlike in Chang's model, an R_{peak} is identified as a PVC peak even if one of the 2nd or the 3rd threshold fails. First threshold is an average RRI computed from the lead II input signal.

First threshold,

$$PVC_{\text{Thr}} = \frac{t_{R_{\text{peak}}}[\text{end}] - t_{R_{\text{peak}}}[1]}{l-1} \quad (4.2.1)$$

where,

l = number of R_{peaks}

$t_{R_{\text{peak}}}[i]$ = location of the R_{peak} at the location $[i]$ in ms

Every RRI of the input signal are compared with the average RRI. If the RRI of the current wave segment (time interval between current and next R_{peak}) is greater than this threshold, current wave is identified as unique. Further conditions will determine if it is a PVC wave or not. Second and third thresholds are more focused on detecting abnormally large positive and negative amplitudes.

4.2.1. Sum of trough (S_T)

Second threshold used in the PVC detection is known as sum of trough. In every iteration, an R_{peak} is considered for PVC detection. In a particular iteration, amplitude of the 50 locations after the current R_{peak} location are added together. If this value is less than zero, that particular peak is detected as a PVC peak.

$$\text{Sum}_T = \sum_{n=1}^{50} \text{amp}[t_{R_{\text{peak}}}[i] + n] \quad (4.2.1.2)$$

where,

$\text{amp}(x) = \text{Amplitude at location } x \text{ in mV}$

4.2.2. Sum of R_{peak} with minimum (Sum_{Min})

Third threshold used in this thesis to detect PVC wave is sum of R_{peak} with minimum. This is a summation equation as defined in equation 4.2.2.1. In any particular iteration, the minimum amplitude between the two consecutive R_{peaks} is added to the current R_{peak} . If this value is less than zero, the current R_{peak} is identified as a PVC.

$$\text{Sum}_{\text{Min}} = \text{min} + \text{amp}[t_{R_{\text{peak}}}[i - 1]]$$

(4.2.2.1)

$$\text{min} = \text{Minimum}(\text{ym}(t_{R_{\text{peak}}}[i]: t_{R_{\text{peak}}}[i + 1]))$$

(4.2.2.2)

where,

$\text{ym} = \text{Denoised input signal.}$

$\text{Minimum} = \text{Minimum amplitude function.}$

If both the thresholds (Sum_{T} and Sum_{Min}) are less than zero, the wave is identified as a PVC, otherwise it is treated as a normal R_{peak} with a wide RRI.

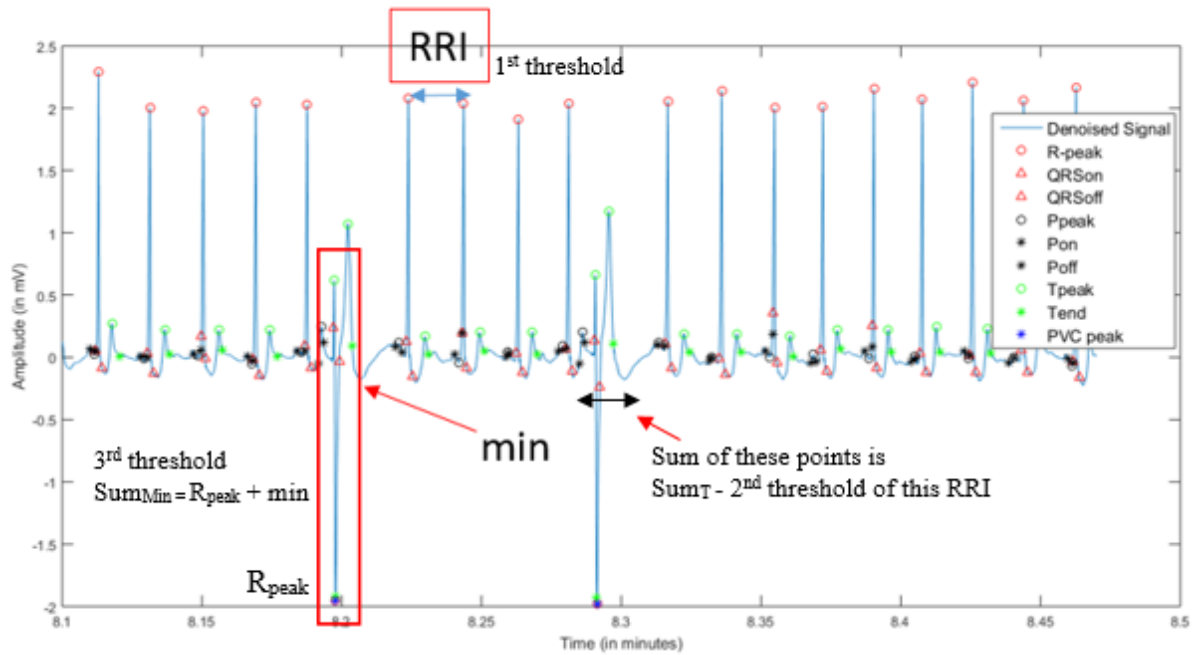

Figure 14 PVC detection thresholds

4.3. 3D heart envelope

This module consists of an anatomically accurate digital 3D heart envelope. The conduction pathway is sketched and potentials are mapped on this heart envelope. Malchenko's heart model [20] or 3D model 1 (Figure 15) mentioned in the literature review (section 2.2.2) is used for this purpose.

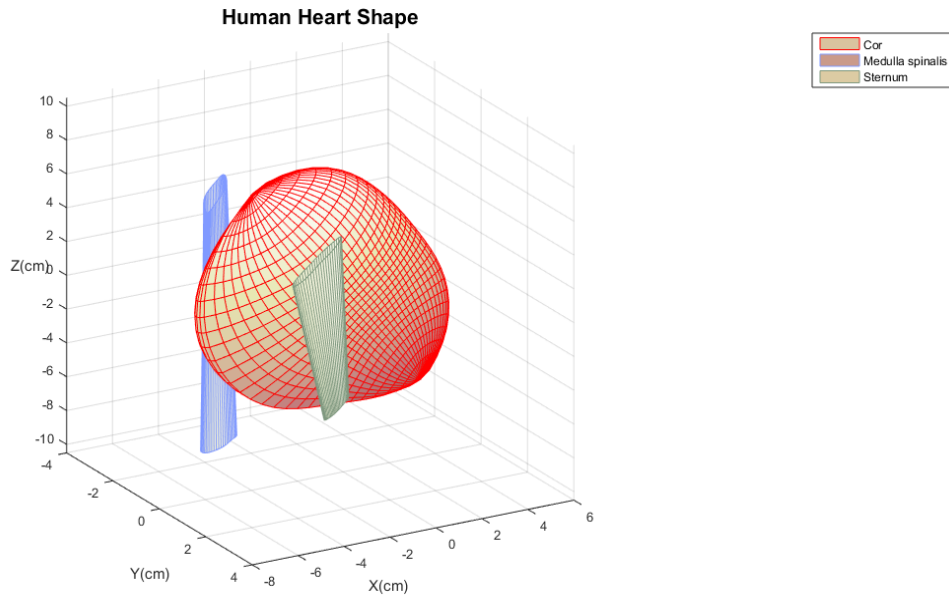

Figure 15 Malchenko's 3D heart model [20]

Planes (Figure 8) along the heart can be easily defined on this heart model since the positions of the sternum and the spinal cord relative to the heart are already defined. All chambers and valves can be viewed from a cross-sectional view along the frontal plane. Visualization of the potential movement is the best in this view since it can show positions of the SA node, AV node and all other components of the conduction pathways. Hence, this view is selected for the proposed system. Information of the sternum and the spinal cord is discarded since they are not relevant for the proposed design. However, three landmarks on the heart model is used to slice the model along frontal plane – top converging point, origin, and the apex. SA node is located inside the high right atrium near the top converging point and the apex of the heart is located at the bottom portion of the 3D model where all the vertical splines converges. According to the Malchenko's model, origin of the heart is the center of the aortic valve [20]. Anterior portion of the model was deleted from this heart model by maintaining these landmark on the frontal plane. Further designing and mapping were conducted on the remaining half (derived 3D heart model).

4.4. Cardiac potential mapping

This module consists of a novel conduction pathway design and a timing information based potential mapping algorithm. Timing information is obtained from the QRS detection module. R_{peak} , P_{on} , P_{off} , QRS_{on} , QRS_{off} and T_{end} along with the denoised signal are the input variables of this module. Information on the PVC peaks are also given as input from PVC detection module as a separate matrix.

4.4.1. Conduction pathways

The conduction pathways consists of multiple components as mentioned before. Position of these components are fixed. As mentioned earlier, origin is the center of the AV valve in Malchenko's model. From the anatomy of the AV node, it is observed that the AV node is located near the AV valve. From the Figure 15, it can be observed that the surface of the heart model is composed of an uneven mesh. The distance between any two adjacent intersections on this mesh will be referred as 'mesh unit' and the minimum distance between any two intersections between the 3rd and the 20th horizontal spline will be referred as 'minimum mesh unit' further in this document. Location of the AV valve and the surface mesh components' dimension are used for the conduction pathway design. Hence the AV node's position is approximated one minimum vertical mesh unit upper to the origin of the derived 3D model, at (-1, 0, 1.7). SA node is defined one vertical mesh unit from the top converging point towards the right atrium at (-4.01, -0.37, 5.84). Co-ordinates for other conduction pathway components are defined with respect to these nodes.

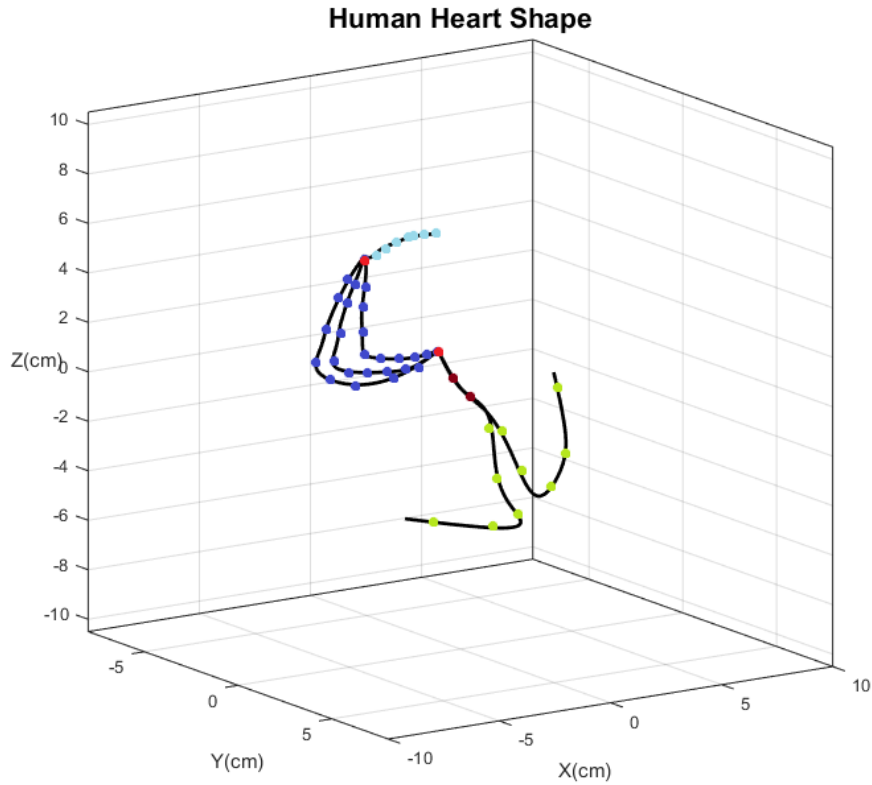

Figure 16 Co-ordinates of the conduction pathways

Figure 16 demonstrates a rough sketch of these paths inside the derived heart model's 3D space. Each component of the conduction pathways are represented by a different color here. The coordinates to sketch these conduction pathways are located either on the curved surface of the heart mode (3D space 1) or located inside the vacant space between the 3D space 1 and the frontal plane where no mesh components are present (3D space 2). See Figure 17 to understand the structure of these 3D spaces.

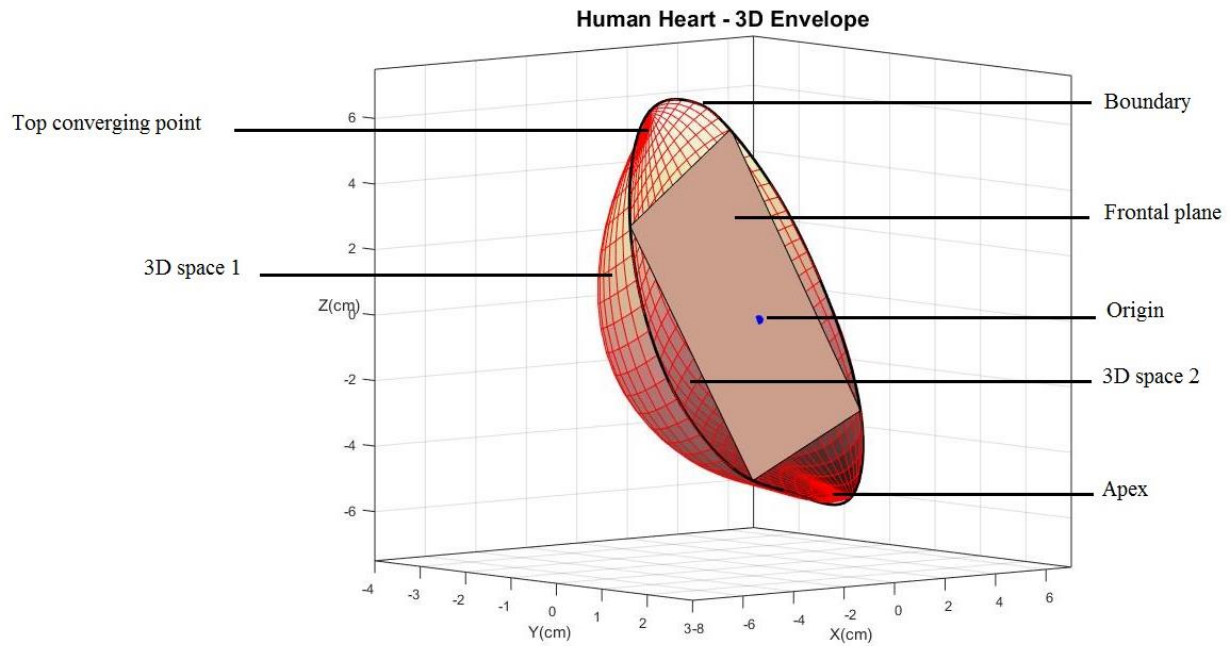

Figure 17 Different regions of the derived heart model

Each of the three internodal pathways and the Bachman's bundle are designed using ten co-ordinates. Coordinates for the Bachman's bundle are defined two units apart on the surface of the mesh towards the left atrium starting from the SA node.

Internodal pathways are defined between the SA node and the AV node using 10 coordinates including these points. These individual paths are defined in 30° angle one another. First coordinate of these three paths is the SA node and the last node is the AV node. Eight points of each of these three paths in between these two nodes lies in the right atrium. Out of the eight points, four points are defined on the 3D space 1 and the remaining four are defined on the 3D space 2. Coordinates in the 3D space 1 is defined two vertical mesh units apart and the coordinates in the 3D space 2 are defined 1 minimum mesh unit apart along the transverse plane. The transverse plane used for this purpose is defined two mesh units below the last point defined in the 3D space 1.

Bundle of Hiss is defined using three points and the two Purkinjee fibers are defined using seven points. The Purkinjee fibers are defined 180^0 apart along the frontal plane in the ventricular region. First point of the bundle of Hiss is the AV node. Other points in the bundle of Hiss and the first three points of the Purkinjee fibers are defined in the 3D space 2. The last coordinate of the bundle of Hiss and the first point of the Purkinjee fibers is a common point. Therefore total five points are present in the 3D space 2. These points are defined two vertical mesh units apart. Since these coordinates are in the 3D space 2, mesh data is not directly available from the model for defining these paths. However, it is possible to measure the dimension of the mesh on the 3D space 1 which is at the same height as these points. This dimension information is used to define these five points at 2 vertical mesh units apart in the 3D space 2. Remaining four points of the Purkinjee fibers are on the 3D space 1 and are placed two mesh units apart, except the last point of each fiber. Last point is placed three mesh units away from the second to the last point.

4.4.2. Timing information and mapping

Four time segments are involved in the mapping of the potentials on the conduction pathway (see Table 2). From the fiducial points exported from the QRS detection module, all four time segments can be calculated.

Table 2 Time variables corresponding to each ECG segment

Annotation	Significance on the heart	Significance on ECG
t_{atria}	Time taken by the potential to travel from the SA node to AV node through intermodal pathways.	P wave
t_{AVnode}	Amount of time the potential stays at AV node.	PQ segment
$t_{\text{ventricles}}$	Time taken by the potential to travel through bundle of His and Purkinje fiber	QRS complex
t_{QT}	Repolarization time	ST segment (known as QT time)

Equations for each time variable is as follows,

$$t_{\text{atria}} = (P_{\text{off}}(i) - P_{\text{on}}(i)) * \frac{1}{f_s} \quad (4.4.2.1)$$

Where,

f_s = Sampling frequency

$$t_{\text{AVnode}} = (QRS_{\text{on}}(i) - P_{\text{off}}(i)) * \frac{1}{f_s} \quad (4.4.2.2)$$

$$t_{\text{ventricles}} = (QRS_{\text{off}}(i) - QRS_{\text{on}}(i)) * \frac{1}{f_s} \quad (4.4.2.3)$$

$$t_{\text{QT}} = (T_{\text{end}}(i) - QRS_{\text{off}}(i)) * \frac{1}{f_s} \quad (4.4.2.4)$$

A marker, which represents the cardiac potential, is moved along the conduction pathway segments for mapping. Inbuilt MATLAB function ‘scatter3’ was used for this purpose. A ‘for’ loop which ranges from the first point to the last point of the conduction pathway segment is used to move the marker along the path. Each iteration of this loop defines the position of the marker. In order to move this marker in the speed of ECG signal, timing information obtained from the QRS module is used (Equations 4.4.2.1 to 4.4.2.4).

Out of the four stages of mapping, the first stage is the mapping of P wave onset to offset. Markers are moved along the internodal pathways (represented in solid blue color in Figure 16) and the Bachmann's bundle (represented in light blue color in Figure 16) during this stage. Mapping speed is adjusted using t_{atria} . The execution is paused for a fraction of this time in each iteration of the loop to ensure that the total mapping time matches with t_{atria} . If the overflow flag ($\text{flag}_{\text{atria}}$) detects the total mapping time exceeds t_{atria} , this delay (Δt_{atria}) is not applied in the further iterations.

Delay,

$$\Delta t_{\text{atria}} = \frac{t_{\text{atria}}}{\text{length}(\text{segment})} - \text{flag}_{\text{atria}} \quad (4.4.2.5)$$

Where,

segment = intermodal pathway variable

$\text{flag}_{\text{atria}}$ = Mapping time overflow flag - atria

The second stage of mapping is the PQ segment. This is implemented by delaying the execution by t_{AVnode} . Since this conduction pathway segment is defined by a single point (AV node), delay can be applied directly at this stage.

QRS complex mapping in the third stage of the potential mapping process is implemented in the same manner as P wave. Marker moves along the bundle of His (represented in maroon color in the Figure 16) and the Purkinje fiber (represented in green color in the Figure 16) at this stage.

Delay,

$$\Delta t_{\text{ventricles}} = \frac{t_{\text{ventricles}}}{\text{length}(\text{segment})} - \text{flag}_{\text{ventricles}} \quad (4.4.2.6)$$

Where,

$$\text{flag}_{\text{ventricles}} = \text{Mapping time overflow flag - ventricles}$$

The fourth stage is the ST segment. Time from the QRS_{off} point to Tend is used to map the potential at this stage. This corresponds to the repolarization time. A delay element with t_{QT} is applied at this stage.

The user is allowed to adjust the speed of the visualization by a scale proportional to the ideal time using a ‘scale’ variable which is multiplied with the time variables. User can visualize the potential movement up to 50x slower than the ideal time which is the time obtained from the signal. This additional feature enables a better visualization of each ECG components.

4.5. Chest lead potential mapping

Chest lead potentials are mapped on a 2D cross sectional image of the heart, displayed in a separate window. As mentioned in the background study, chest lead vectors are more negative near the Wilson’s central limit terminal (assumed as origin here). A positive potential is expected near the corresponding electrode and a negative potential is expected near the center of the heart. Denoised chest lead potential (V1 in most of the MIT-BIH arrhythmia database) from the QRS detection module is the input signal of this module.

A marker is moved along a line segment which represents the lead vector. Direction of this line segment will change with the selection of the chest lead (Figure 8). Position of the marker on this line segment depends on the potential’s amplitude. More negative amplitudes are placed near the center of the heart and more positive amplitudes are placed near the

exterior portion of the torso in the direction of the lead where the line segment ends. A radiograph image of the torso across the transverse plane (Figure 18) is used for this purpose.

Figure 18 Cross sectional image of the chest and precordial leads [24]

For the smooth movement of the markers along the chest lead vector, values from the amplitude range of the input signal is distributed evenly along the equal segments of the vector.

5. Results

5.1. 3D envelope

Figure 17 shows the Malchenko's 3D heart model and the cross section along the frontal plane. SA node is defined near the top node where all the vertical splines converge. AV node is sketched on the line which connects the top node, origin and the vertex. The origin can be identified as the point where all the horizontal splines converge (Figure 19 B). The apex of the heart can be observed at the bottom where all the vertical splines converge.

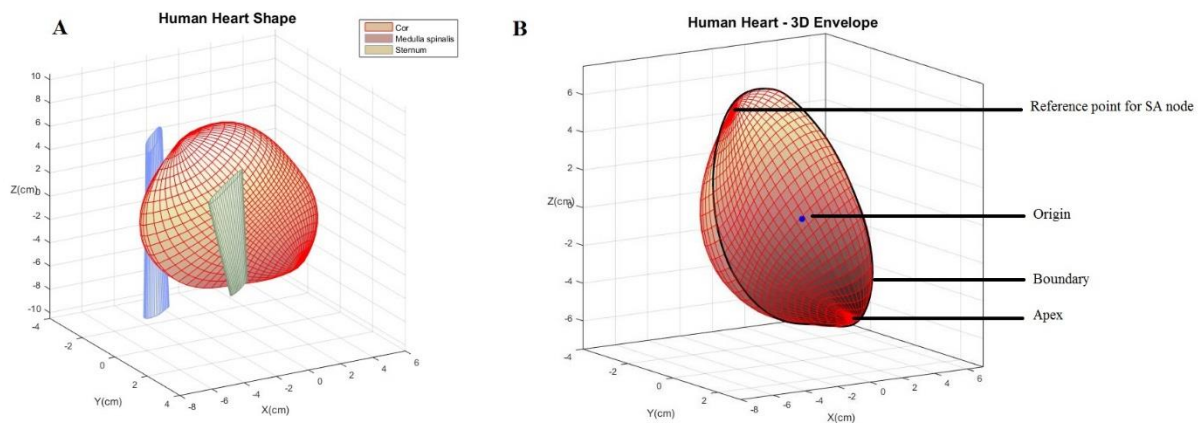

Figure 19 (A) 3D heart, and (B) its cross section along frontal plane

The conduction pathways used in this system are shown in Figure 20. The conduction pathways designed using the co-ordinate information is on the left panel and the right image shows the relationship of the conduction pathways and cardiac anatomy in the masked 3D heart model.

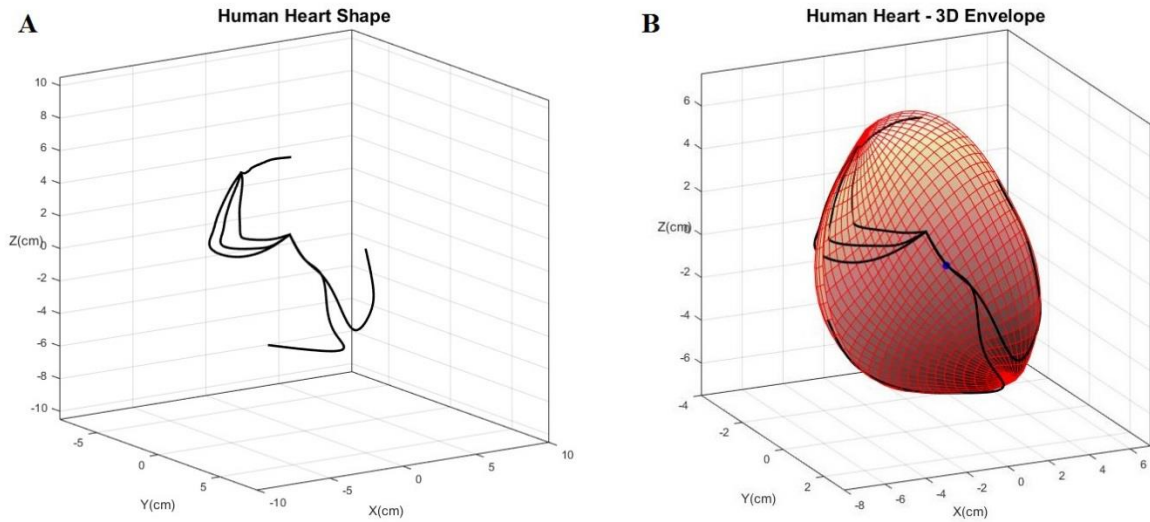

Figure 20 (A) Conduction pathway, (B) Conduction pathway mapped on to the masked 3D heart model (right)

5.2. Input signal

Selected recordings from the MIT-BIH arrhythmia database are used as input signals to test the system. Table 4 is the list of all the signals in this database with at least one PVC peak. PVC locations listed in the table is an approximate position of the peak. An offset of few seconds is expected in the location of the peaks.

Table 3 ECG signals with PVC from the MIT-BIH database

Signal	Leads	PVC locations from the database (in min)	Other arrhythmias present
100	II, V5	25.13	Atrial Premature Complexes (APC),
105	II, V1	7.57, 26.45	Unclassifiable beats
106	II, V1	4.23	Only PVC
107	II, V1	12.30, 19.54, 25.52	Paced beats
108	II, V1	0.22, 4.51, 8.13, 18.08	APC, Junctional rhythm, Blocked APC

109	II, V1	0.13, 1.28, 4.46, 14.01, 17.13, 19.21, 28.03, 29.10	Left Bundle Branch Block (BBB)
111	II, V1	8.31	Left BBB
114	V5, II	1.20, 3.39, 3.56, 4.35, 8.31, 11.37	APC, Junctional premature
116	II, V1	1.31, 12.32	APC
118	II, V1	3.39, 9.23, 22.32, 25.41, 26.23	Right BBB, Blocked APC, APC
119	II, V1	1.55	Only PVC
121	II, V1	16.48	APC
123	II, V5	25.11, 27.41	Only PVC
124	II, V4	26.03, 27.41	Right BBB, APC, Junctional premature, Junctional escape
200	II, V1	29.18, 29.51	APC
201	II, V1	20.16, 24.15	APC, Aberrated APC, Junctional premature, Junctional escape, Blocked APC
202	II, V1	10.16, 12.24, 12.41, 21.10	APC, Aberrated APC, Atrial fibrillation, Atrial flutter
203	II, V1	22.02, 24.04	Aberrated APC, Unclassifiable beats
205	II, V1	16.03, 16.15, 19.57, 27.57	APC
207	II, V1	Test at 25.36	Left BBB, Right BBB, APC, Ventricular flutter, Ventricular escape
208	II, V1	28.58	Supraventricular Tachycardia (SVT), Unclassifiable beats
209	II, V1	12.57	APC
210	II, V1	20.33, 29.15	Aberrated APC, Ventricular escape
213	II, V1	3.39, 15.05, 17.55, 24.43, 28.56	APC, Aberrated APC
214	II, V1	0.30, 2.21, 27.52	Left BBB, Unclassifiable beats
215	II, V1	9.46, 15.58	APC
217	II, V1	0.33, 1.23	Paced beats, Pacemaker fusion
219	II, V1	2.49, 24.43, 28.55	APC, Blocked APC
221	II, V1	0.00, 19.12	Only PVC
223	II, V1	Test at 29.51	APC, Aberrated APC, Atrial escape
228	II, V1	0.50, 4.35, 19.18	APC
230	II, V1	29.04	Only
231	II, V1	Test at 2.24	Right BBB, APC, Junctional escape
233	II, V1	0.11, 2.43, 16.20, 18.02	APC
234	II, V1	17.02, 21.26	Junctional premature

Even though only those recordings with PVCs are analyzed in this thesis, it is important to note that this visualization system can process any limb lead and chest lead as input. Figure 21 shows the first minute of signal 101 as displayed in the PhysioBank ATM [21]. Output waveform of the QRS detection module with all the fiducial points within this time interval can be observed in Figure 22.

Figure 21 Signal 101 with no PVC (Upper: Lead II, Lower: V1)

Figure 22 Output waveforms of QRS detection module for signal 101 (A: Lead II, B: V1)

Figure 23 is the signal 114 between 1 minute and 2 minutes of the recording. PVC peak at 1.20minutes can be observed in the figure inside the red box. A more comprehensive investigation of the PVC detection algorithm will be provided in the Section 5.4.

Figure 23 Signal 114 (Upper: Lead V5, Lower: II)

5.3. Mapping

Timing information obtained from the QRS detection module is the input to the mapping module. A sample of this timing information from 5 different time intervals is listed in Table 4. Sampling frequency of the input signals are 360Hz. The fiducial points from the signal 114 were used to obtain these values.

Table 4 Timing information form lead II

Segment	Location	Time interval	Time from the input waveform (in ms)
P wave	Atria	1	100
		2	127.8
		3	116.7
		4	88.9
		5	113.9
PQ	AV node	1	25
		2	22.2
		3	16.7
		4	5.6
		5	5.6
QRS	Ventricles	1	130.6
		2	130.6
		3	116.7
		4	147.2
		5	133.3
ST	Repolarization	1	391.7
		2	383.3
		3	386.1
		4	313.9
		5	313.9

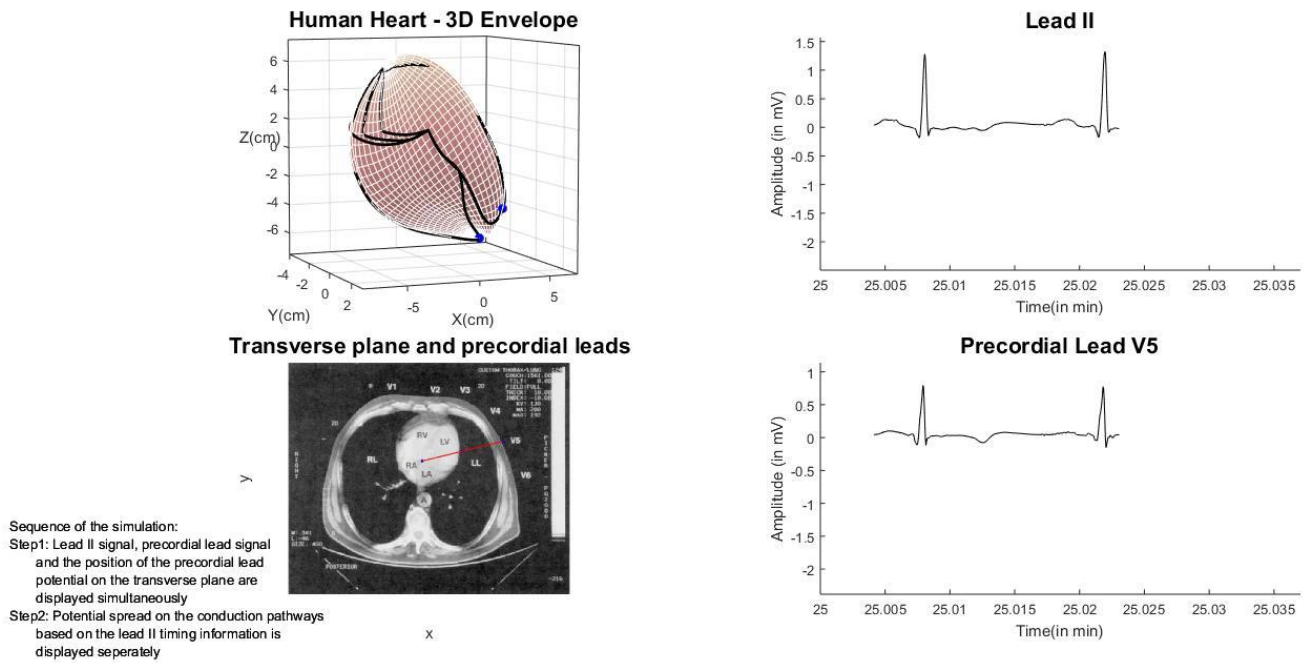

Figure 24 Output window

Figure 24 is the output window of the implemented visualization system. The top left image of the output window is the 3D heart envelope mounted with the conduction pathway, top right portion displays the lead II signal, bottom left image is a cross section of the heart on which the chest lead potential is mapped and the bottom right portion displays the corresponding chest lead signal. Simulation of the lead II and the precordial lead are not designed to execute simultaneously, so the user is only able to see conduction path information for lead II or the vector amplitude for the precordial lead at a time. Sequential events involved in the mapping of an ECG complex are as follows:

1. P-wave segment is displayed on both signal display windows (top right and bottom right portions of the output window). Chest lead potential is mapped on the chest lead vector at the same time (bottom left of the output window).

2. Markers which represents the cardiac potential are moved along the internodal pathways.
3. PQ segment is displayed and the corresponding chest lead potential is mapped on the chest lead vector.
4. Marker movement is paused at the SA node for t_{AVnode} time.
5. QRS complex is displayed and the corresponding chest lead potential is mapped on the chest lead vector.
6. Markers are moved along the two Purkinje fibers through bundle of His.
7. ST-segment and the T-wave are displayed and the corresponding chest lead potential is mapped on the chest lead vector.
8. Potential mapping is paused for t_{QT} time.

A synopsis of this sequence can be observed at the bottom left corner of the output window. The user can easily understand the simulation procedure with the help of this text box.

5.3.1. Lead II mapping

Signal 100 is used as the input signal for all the following simulation results in this section. This signal is 30.06 minutes long and consists of one PVC peak. Figure 25 to Figure 28 are images of the output window during various stages of the simulation. Figure 25 is a P wave simulation. Blue marker can be observed on the internodal pathways. A fourth marker can be observed on the Bachmann's branch in the left atrium.

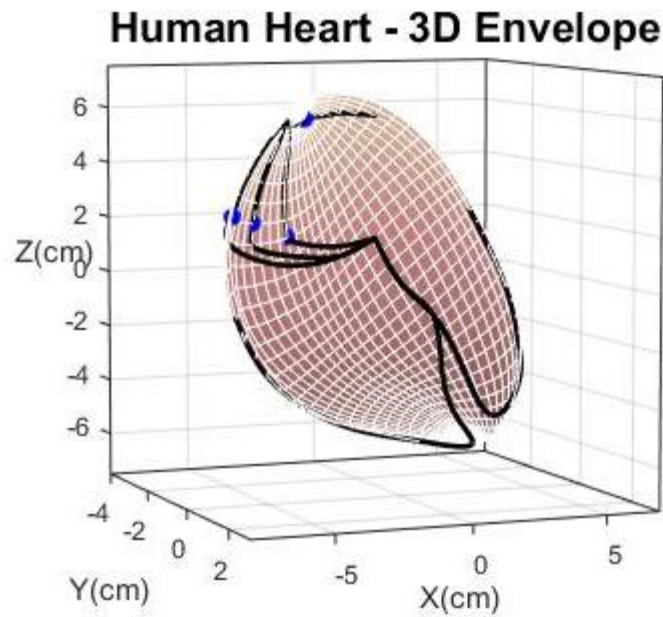

Figure 25 Mapping of the P wave on the conduction pathways

The marker is paused at the SA node during the PQ segment simulation. The marker can be observed on the conduction pathways (see Figure 26).

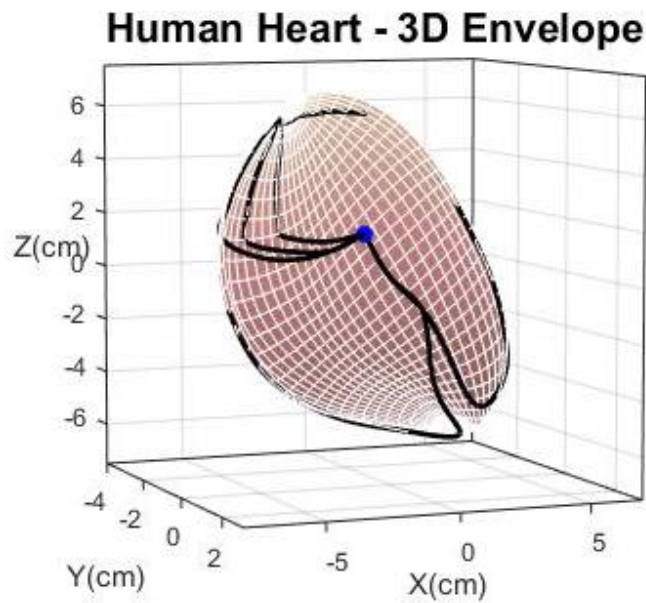

Figure 26 Mapping of the PQ segment on the conduction pathways

The QRS complex between 25.05min and 25.07min can be observed from the Figure 27. Corresponding potential movement which is mapped on the Purkinje fiber segment of the conduction pathway can also be observed on the left.

Figure 27 Mapping of the QRS complex on the conduction pathway

Figure 28 is shows mapping of the ST segment on the conduction pathway. This is the repolarization time in which heart muscles contracts to squeeze blood outside the ventricle and then relaxes. Potential mapping is paused for t_{QT} seconds.

Figure 28 Mapping of the ST segment on the conduction pathway

5.3.2. Precordial lead mapping

Potential mapping on the chest lead vector, and the signal display take place simultaneously. Chest lead signal can be observed in the bottom right side of the output window. Cross sectional image of the thorax along the transverse plane can be observed in the bottom left side of the same window. Chest lead vector can be observed in the direction of V5. Potential is mapped along this vector. Signal 100 with V5 lead is used in this section to demonstrate the chest lead mapping. Figure 29 to Figure 32 shows various stages of the simulation. Figure 29 shows the potential mapping of a P wave. It can be observed that the red line is pointing towards the V5 electrode. This line is the lead vector for the corresponding input signal. A green marker can be observed on this vector which represents the potential's position at a given time.

Transverse plane and precordial leads

Precordial Lead V5

Figure 29 Chest lead potential mapping during P wave

Figure 30 demonstrates the potential mapping of an R_{peak} . Ideally, the maximum value in a normal ECG complex will be its R_{peak} which is a positive amplitude. As mentioned earlier, the center of the heart is more negative and the exterior of torso is positive according to the central limit theorem. Potential's position can be observed near the V5 electrode.

Transverse plane and precordial leads

Precordial Lead V5

Figure 30 Chest lead potential mapping during an R_{peak}

In Figure 31, a zero potential from the PQ-segment is mapped on the chest lead vector. Green marker can be seen near the middle portion of the vector.

Transverse plane and precordial leads

Precordial Lead V5

Figure 31 Chest lead potential mapping of a PQ segment

The mapping of a negative amplitude from a PVC peak is demonstrated in the Figure 32. It can be observed that the green marker corresponding to the potential's position is near the center of the heart.

Transverse plane and precordial leads

Precordial Lead V5

Figure 32 Chest lead potential mapping during a negative amplitude

5.4. PVC detection and mapping

PVCs are identified using the PVC detection algorithm as described in the methods section. Identified PVCs are labelled using a blue star on the output waveform as shown in

the Figure 33. PVC peak at 25.13 minute of the signal 100 is the identified peak in this figure. An offset of few seconds can be observed in the identified peak as mentioned in the previous section.

Figure 33 Detected PVC peaks on the signal 100 (Upper: Lead II, Lower: V5)

Only one lead signal is necessary for the algorithm to detect PVC peaks. Lead II signal is selected for this purpose as in the reference document [19]. Amplitude corresponding to this point is labelled as a PVC peak on the output waveform of the chest lead. Therefore, chest lead signal’s output waveform is not used in the evaluation of the PVC peak detection

module. Figure 34 and Figure 35 are the lead II output waveforms of the signals 114 and 119 respectively. PVC at 8.31 minute of the signal 114 and uniform PVC peaks at 1.55 minutes of the signal 119 can be observed in these images.

Figure 34 PVC peaks on signal '114' near 8.31min

Figure 35 PVC peaks on signal '119' near 1.55min

Figure 36 shows the mapping of PVC on the heart's envelope. Color map is changed from a solid pink to a range of colors during a PVC to draw attention to the aberrant beat. Since the PVC origin is unpredictable, the red color shows the region in which the potential could be generated. Other regions are colored differently since they do not generate a PVC. If the number of identified PVC waves is close to the number of PVCs in a given period of time, algorithm is robust. Results of this efficiency test is recorded in the Table 5. This test was performed for all signals in the database with PVC. Results of few signals are recorded in the Table 5. It is also observed that the system fails to read certain signals within certain time intervals due to unidentified noise source.

Figure 36 PVC mapping

Table 5 PVC peak detection results

Signal	Time interval (in minutes)	Number of PVC peaks present in this range	Number of identified PVC peaks
100	25 to 26	1	1
114	1 to 5	13	12
116	1 to 5	11	5
119	0 to 5	84	48
200	29 to 30	20	19
205	16 to 17	3	2
234	17 to 22	2	2

6. Analysis and Discussion

This section discusses the efficiency of the implemented system. Output of the PVC detection algorithm is compared with the published results¹⁷. Three major components analyzed are the accuracy of the 3D envelope structure, mapping efficiency and the speed.

First component is the cross section of the 3D heart envelope. It can be observed that the heart is sliced along the mid-plane in order to obtain the cross section. Origin and other two points where all the vertical lines are merged can be observed from the cross sectional image of the 3D heart model (see Figure 17). Recall from the literature review section the cardiac model used for visualization is based on a volumetric reconstruction from MRI slices through the heart. The horizontal rings or layers represent the boundaries of the MRI slices of the heart. Among the three points, the top point is the convergence point before the first layer of the heart model. Bottom point is the apex of the heart. The origin can be observed as a blue dot at the center of the 3D space. All three points and the boundary of the 3D space are on the same plane as seen in the Figure 17. This implies that the heart is sliced along the right plane.

Second component is the mapping efficiency. Factors that determine the efficiency of a simulation software are its accuracy and speed. While the total simulation time or the processing time determines the speed of the system, accuracy is determined by the mapping time of each event (P wave onset and offset, PQ interval, QRS complex duration, and QT intervals) individually. Among the four ECG segments, mapping time of the P wave onset and offset, and the QRS complex are the only factors which can influence the total mapping time. Mapping time of PQ interval and QT interval are direct delay statements. A marker is paused at each point of an intermodal pathway in order to map P wave onset and offset segment using t_{atria} . Delay of a fraction of the t_{atria} is applied at each point. This process can create some additional delays due to various factors including time estimation error, and

computational delay of MATLAB. Since the mapping of the signal in the ventricles are carried out in the same manner, similar delays are anticipated in the mapping of $t_{\text{ventricles}}$ as well. These additional delays will be referred as ‘mapping delays’ further in this document. Table 6 is a record of atrial and ventricular mapping time for the three recordings provided in the Results section. N is the number of ECG components (P-waves for the atrial mapping delay and QRS complexes for the ventricular mapping delay) present in the given signal length of the corresponding signal. ΔN is the number of ECG components with a mapping delay and $t_{\Delta N}$ is the mapping delay in milliseconds. Maximum $t_{\Delta N}$ among ΔN ECG components is only listed in this Table since lesser delays does not and any value in the analysis of mapping delays.

Table 6 Atrial and Ventricular mapping delays

ECG component	Signal length (in s)	Mapping delay					
		Signal 100		Signal 119		Signal 234	
		ΔN {N}	Maximum $t_{\Delta N}$ (in ms)	ΔN {N}	Maximum $t_{\Delta N}$ (in ms)	ΔN {N}	Maximum $t_{\Delta N}$ (in ms)
P-wave (Atria)	10	3 {10}	69.5	1 {9}	62.7	1 {13}	7.6
	20	4 {22}	62	3 {19}	29.3	1 {28}	9.6
	30	10 {36}	60.1	2 {30}	57.4	0 {44}	0
	40	8 {48}	31.5	2 {42}	27.5	0 {59}	0
	50	14 {60}	82.4	1 {52}	23.9	1 {75}	8.2
QRS Complex (Ventricle)	10	0	0	0	0	0	0
	20	0	0	0	0	0	0
	30	0	0	0	0	0	0
	40	0	0	0	0	0	0
	50	0	0	0	0	0	0

Mapping time of the three signals for five different signal lengths are compared for this study. Signal 100 and signal 119 are signals with PVCs, while signal 234 does not have a PVC. Time interval considered for 100 and 119 contains at least one PVC peak. It is observed that the atrial mapping delay ranges between 5ms and 90ms. Maximum mapping delay was

consistently observed at the first P wave. Surprisingly, ventricular mapping time is observed as zero at every stage of simulation. This segment of the conduction pathways has fewer points, hence minimum delay. The bundle of His and Purkinje fibers are the only components of the conduction pathway in the ventricular region. These are designed using fewer points due to a more linear structure as compared to the internodal pathways. Hence, fewer iterations are required to move the marker along this structure. In addition, unlike internodal pathways with three paths and a Bachmann's branch, Purkinje fiber only has two paths. This makes it less computationally intensive to move the marker.

Third component to analyze is the PVC detection schema. Signals 100, 114, 116, and 119 were used in the reference research (Chang's model [19]) to test the algorithm. Response of the system for these same signals are analyzed here to verify the efficiency of the PVC detection algorithm. Figure 37 to Figure 40 are the output waveforms of 100, 114, 116 and 119 respectively. Characteristics of these signals were available from the Physionet database [21] [22].

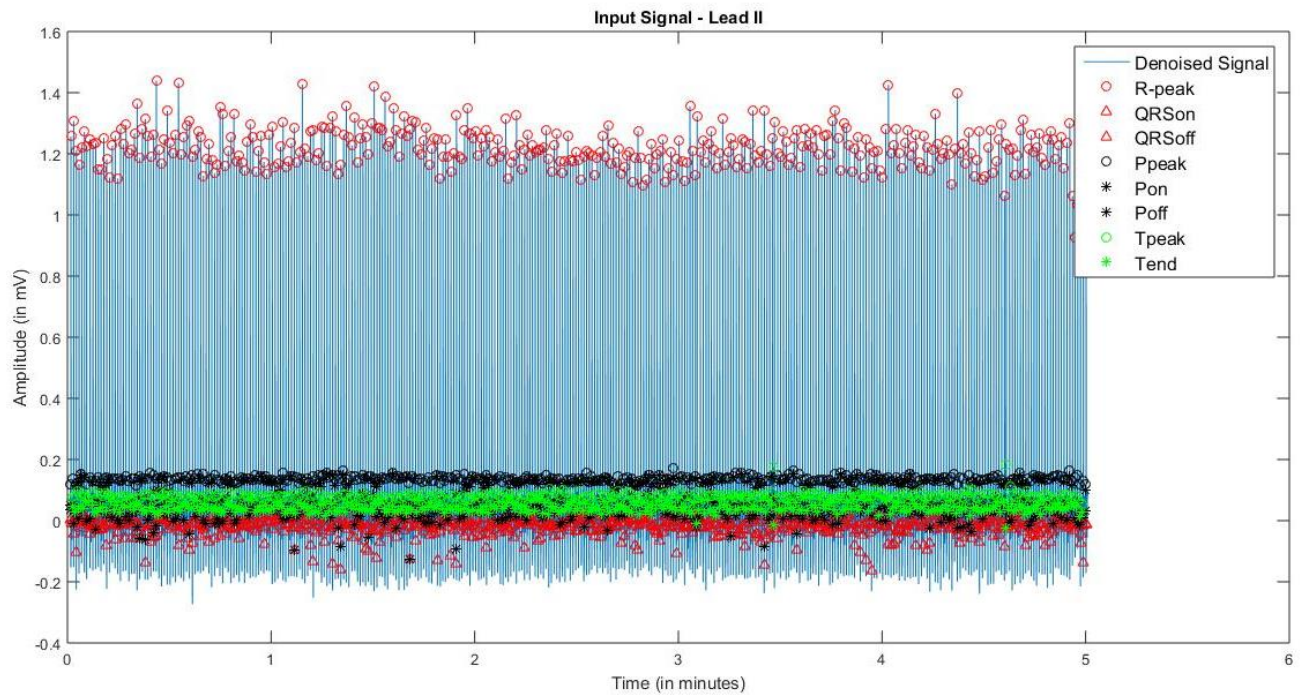

Figure 37 Signal 100 - Lead II (First 5 minutes)

Figure 37 is an image of the first 5 minutes of the signal 100. According to the signal properties, no PVC is present in this segment of signal 100. PVC peaks cannot be observed in this output waveform as well. This implies that the PVC detection module was successful in discarding non-PVC peaks for this input signal.

Figure 38 Signal 114 - Lead II (First 5 minutes)

13 PVC peaks are present in the first 5 minutes of the signal 114. It can be observed from the Figure 38 that the system was able to detect all PVC peaks. However, in certain cases if the last R_{peak} is a PVC and if the whole PQRST information of that particular ECG complex is not available within the signal length, the algorithm will not identify it as a PVC. These peak can be detected if plotted separately with a wider signal length. The undetected PVC peaks will bring down the success rate of the PVC detection algorithm. This implies that the signal length can influence the efficiency of the PVC detection module. Only parameter changed to detect the signal is the number of R_{peaks} . Since number of R_{peaks} changed, average RRI also changed. This leads to more accurate detection of the PVC peaks. PVC detection results obtained for the other two input signals can be observed from the Figure 39 and Figure 40. From the Figure 40 it can be observed that the algorithm failed to detect a considerable amount of PVC peaks for the signal 119. It can also be observed that the number of PVC peaks were really high during this range. Therefore, the average RRI of the total signal length

will skew towards the average RRI of the PVC peaks. Thus, the algorithm detects only those signals which are higher than this skewed average RRI as PVC peaks. This is a limitation of the first threshold used in the implemented algorithm.

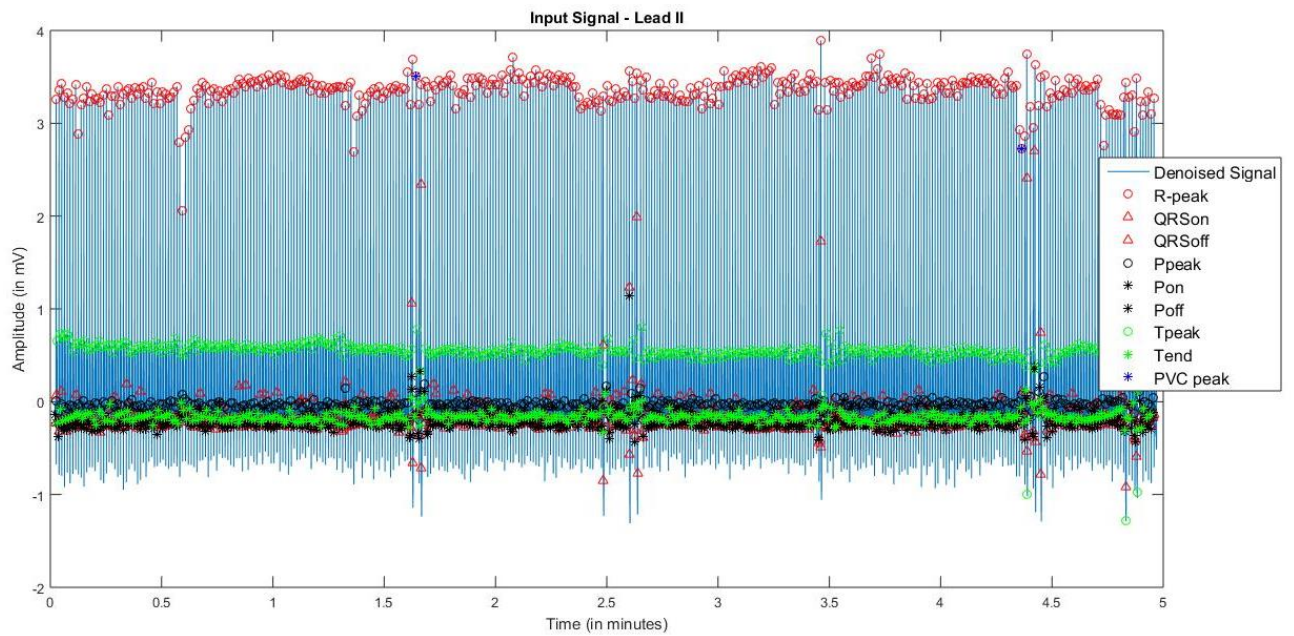

Figure 39 Signal 116 - Lead II (First 5 minutes)

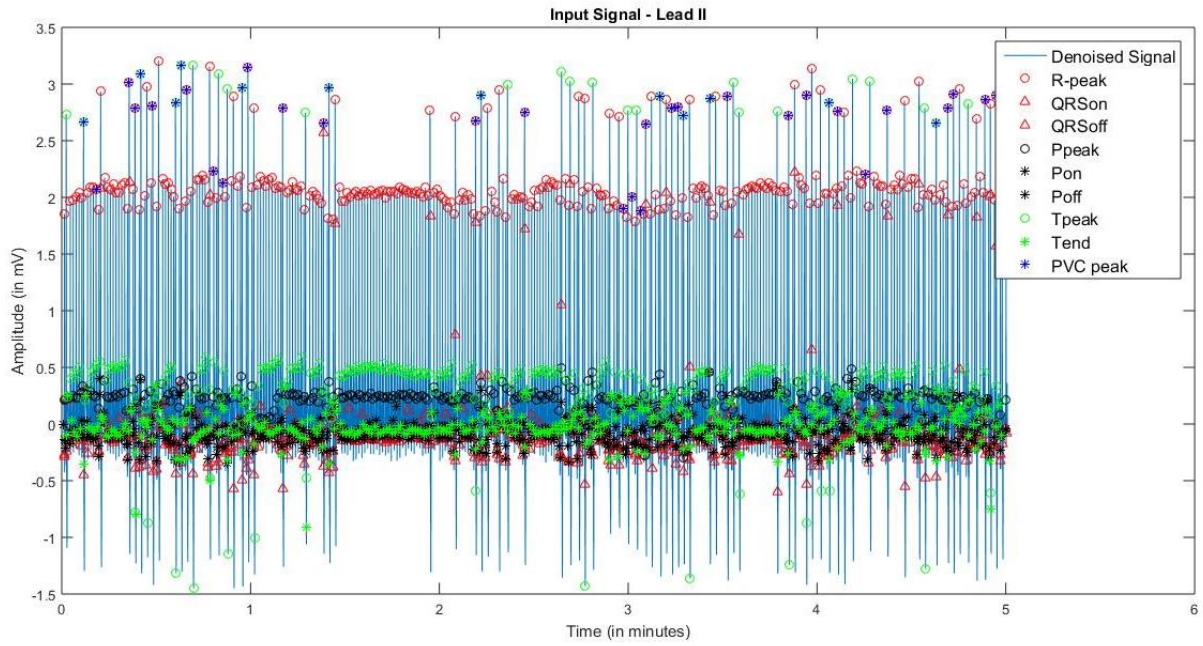

Figure 40 Signal 119 - Lead II (First 5 minutes)

Tables 7, 8, 9, 10, and 11 are the specificity and sensitivity analysis of the PVC detection algorithm for any 5 minutes of these four signals in which at least a PVC peak is present. If a PVC peak is expected and detected, it is counted as true-positive, if a PVC is not expected but detected, it is a false-positive, if a PVC peak is expected but not detected, it is a false-negative and if a PVC peak is not expected and not detected, it is a true-negative. The accuracy, specificity and sensitivity of the algorithm can be obtained using the equations 6.1 to 6.3. Figure 41 shows the true positive analysis chart. Table 7 to Table 10 can be interpreted using this figure.

		R peaks present in the given range	
		Condition positive if PVC	Condition negative if regular R peak
PVC peak detection	Detected	True positive	False positive
	Not Detected	False negative	True negative

Figure 41 True positive rate analysis chart

Table 7 True positive analysis on signal 100

	Condition positive	Condition negative
PVC detected	1	0
PVC not detected	0	369

Table 8 True positive analysis on signal 114

	Condition positive	Condition negative
PVC detected	12	1
PVC not detected	0	264

Table 9 True positive analysis on signal 116

	Condition positive	Condition negative
PVC detected	5	5
PVC not detected	3	375

Table 10 True positive analysis on signal 119

	Condition positive	Condition negative
PVC detected	37	41
PVC not detected	9	241

Sensitivity,

$$\text{Sensitivity} = \frac{\Sigma \text{True positive}}{\Sigma \text{Condition positive}} \times 100 \quad (6.1)$$

Specificity,

$$\text{Specificity} = \frac{\Sigma \text{True negative}}{\Sigma \text{Condition negative}} \times 100 \quad (6.2)$$

Accuracy,

$$\text{Accuracy} = \frac{\Sigma \text{True positive} + \Sigma \text{True negative}}{\Sigma \text{Condition positive} + \Sigma \text{Condition negative}} \times 100 \quad (6.3)$$

Table 11 PVC detection algorithm efficiency study

Signal	This research			Chang's model [19]
	Specificity	Sensitivity	Accuracy	Accuracy
100	100%	100%	100%	100%
114	100%	99.62%	99.64%	Not Available
116	62.6%	98.68%	97.94%	Mean accuracy of 116 and 119 is 72.96%
119	80.43%	85.46%	84.75%	
Average			95.58%	86.48%

The specificity and sensitivity calculated for these four signals are listed in the Table 11, along with the accuracy values published in Chang's research [19]. It can be observed that the average accuracy of the PVC detection algorithm implemented in this system is 9% more than that of the Chang's model. Combination of the thresholds to filter non-PVC peaks were altered in the design implemented for this thesis. In Chang's model, third threshold is only applied if the second threshold fails to detect a PVC. However, in the proposed design, second and third thresholds are applied even if either one fails to detect a PVC. Therefore, there is more probability to obtain more true-positives. The increase in the average accuracy proves that the changes made to the algorithms improved the performance. However, PVC detection algorithm tends to change its performance with varying signal length. The system detects PVCs more accurately when the signal length is smaller. The factor influencing this tendency is the first threshold. As mentioned in the methods section, the first threshold is an average value of R_{peak} to R_{peak} intervals. When only few samples are present to compare with this threshold, peaks will remain unique. Thus it can be easily identified. For example, PVC peaks were identified more accurately when a shorter signal range was selected within the first 5 minutes of the signal 119.

7. Conclusion

A tool for 3D visualization of cardiac excitation was implemented using MATLAB as a second phase of the educational tool development project during the course of this thesis. Main features focused in this implementation were a 3D heart model, conduction pathway identification, accurate timing information, and PVC detection. Timing information was obtained from the wavelet transform based QRS detection module implemented in the first phase¹. An MRI reconstructed 3D heart was used to develop suitable heart envelope and the conduction pathway.

The 3D heart was sliced along the frontal plane and SA node, AV node and conduction pathway components were defined for mapping purpose using co-ordinate functions and 3D spline functions. Timing information obtained from the QRS detection module was used to move markers along the internodal pathways and Purkinje fiber. It is observed that the atrial mapping delay was in the range of 5ms to 83ms. This is a small fraction compared to the total simulation time. Ventricular mapping delay was observed as zero due to the lighter structure of the ventricular segments of the conduction pathways. One chest lead was used to determine the location of the potential from a top view or a cross sectional view along the transverse plane. Even though the total simulation time was affected by several external factors, it is observed that the change in this time is linear and correlated with the simulation speed scaling factor as expected.

Two additional thresholds other than the first average R_{peak} to R_{peak} time interval threshold were used to implement the PVC detection module: sum of trough and sum of R_{peak} with minimum. PVCs with wider R_{peak} to R_{peak} interval were detected using sum of trough threshold and PVCs with unique amplitude features were detected using the sum of R_{peak} with minimum threshold. Efficiency of this detection algorithm is compared with the Chang's

model which uses same thresholds in different combination to detect PVCs. Signals 100, 114, 116, and 119 were used to detect the PVC peaks as in Chang's model. Even though the success rate in detecting the PVC peaks of the first two signals were high, the success rate was comparatively low in the other two signals. It is also observed that the success rate increases with shorter signal length. An adaptive average RRI as threshold 1 would help in solving this issue.

The implemented 3D visualization system was successful in mapping the potential on the defined conduction pathway. The PVC detection module was also successful in distinguishing between a PVC and a non PVC wave with nearly 95% accuracy. However, total simulation time is affected by several external factors like computational delays and computer specification limitations. More chest lead inputs can determine more accurate position of the potential on the transverse plane. This is desired in the future work of this project.

8.7. Main function with conduction pathways and the cardiac potential mapping

```

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
% Conduction3D()
%
% Author      : Pranav Sreedharan Veliyara
% Advisor     : Dr. Samhita Rhodes
% Project     : Master's thesis at Grand Valley State University
% Thesis title : Visualization of the cardiac excitation and PVC
%              arrhythmia on a 3D heart model
% Code version : 1.0
% Published year: 2017
%
% Description : This is the main function used in the development of
%              the simulation tool.
%              This function consists of five modules. They are:
%
%              MODULE 1 - Importing the timing information from
%              the QRS detection module.
%              MODULE 2 - The 3D heart envelope and the conduction
%              pathways.
%              MODULE 3 - Transverse plane and the precordial
%              vector.
%              MODULE 4 - Running plot of the lead II signal

```

```

%           (Channel 1).
%           MODULE 5 - Running plot of the precordial lead
%           signal (Channel 2).
%           MODULE 6 - Mapping the cardiac potential on the
%           conduction pathways.
%
% Input      : InputFile - (string) Signal name as published in the
%                   MIT-BIH arrhythmia database.
%                   n, v   - These variable internally assigns
%                   appropriate channel to lead II and the
%                   precordial lead
%                   signals. Channel 1 always has the lead II
%                   signal and channel 2 always contains the
%                   precordial signal.
%                   lead   - Precordial lead selection.
%                   Start_point, End_point - (integer) X-coordinate
%                   information of the first sample and the
%                   last sample of the input signal.
%                   scale  - Lets the user to adjust the simulation
%                   speed. Grater the scale, slower the
%                   simulation. Mapping time is multiplied this
%                   scale factor.
%
% Note       : Variable those are labeled (in comments) as
%                   'Test time variables' are used to evaluate the
%                   mapping delay, simulation speed and the computational
%                   delay of the system. Mapping delay is explained in
%                   detail in the 'Results' and 'Analysis' section of
%                   the thesis report.

9. Appendix II – QRS detection model

9.1. Denoising

Signals are always mixed with some amount of noise. There are numerous sources for noise, especially in the case of physiological signal acquisition. Physiological signals like ECG and EEG are low amplitude signals which is vulnerable to various noises. Denoising reduces the baseline wandering, power line interference and other high frequency noises in the ECG signal. Baseline wandering is a low frequency noise in the range of 0Hz to 1Hz. Denoising method implemented in Eric's model to remove baseline wandering uses a Symlet wavelet to decompose the input ECG signal into 8 levels. Then the reconstructed low frequency components in the range of baseline wandering noise is subtracted from the raw input ECG signal.

In addition to baseline wandering, this denoising algorithm is capable of cancelling other common noises like powerline interference and some high frequency noises. Soft thresholding method described in the following equations are used to get rid of these noises.

Soft thresholding technique,

$$c\hat{D}_j = \begin{cases} \text{sign}(cD_j)(|cD_j - t|), & |cD_j| \geq t \\ 0, & |cD_j| \leq t \end{cases} \quad (10.1.1)$$

Where,

$c\hat{D}_j$ = the detail coefficient at level j after thresholding

cD_j = the detail coefficient at level j before thresholding

t = threshold

Threshold,

$$t = \sigma \sqrt{2 \log(N)} \quad (10.1.2)$$

$$\sigma = \frac{\text{median}|cD_j|}{6.457} \quad (10.1.3)$$

Where,

N = the length of the ECG signal

Coefficient of decomposed signal (using Symlet wavelet) at level j is represented as cD_j.

Denoised signal is reconstructed using the inverse wavelet transform.

9.2. QRS-complex detection

QRS complex detection algorithm has two stages – R_{peak} detection and QRS complex on and off detection. Denoised signal is again decomposed using Symlet wavelet (sym5) into 8 levels. Fiducial points R_{peak}, QRS_{On} (QRS onset) and QRS_{Off} (QRS offset) points are extracted from this decomposed denoised signal. Frequency range of each level of decomposed denoised signal listed in Table 12.

Table 12 Decomposed signal coefficients and corresponding frequencies

Coefficient Level	Frequency Range (Hz)
cD ₁	90 - 180
cD ₂	45 - 90
cD ₃	22.5 - 45
cD ₄	11.25 - 22.50
cD ₅	5.63 - 11.25
cD ₆	2.81 - 5.63
cD ₇	1.41 - 2.81
cD ₈	0.70 - 1.41
cA ₈	0 - 0.70

Frequency range of a normal QRS complex is 10Hz – 40Hz. Decomposed components in this frequency range ($cD_3 - cD_5$) is reconstructed using Inverse Discrete Wavelet Transform method (IDWT). Absolute value of the sum of these reconstructed frequency components (y_m) are used to identify R wave. An adaptive windowing (0.5s width) is applied on this signal to approximate the positions of R_{peaks} . If a maximum value is found within 0.15s to 0.35s which is greater than the threshold, it is identified as an R_{peak} . Adaptive thresholding used in this peak detection method which updates for every 5 seconds. Signal is checked with a second threshold if any identified consecutive peaks are in a distance greater than 1.4 times the average RR interval.

Threshold,

$$\text{thresh}(i) = \alpha \max(y_m(i : i + s)) \quad (10.2.1)$$

Where,

$$\alpha = 0.35 \text{ for first threshold}$$

$$\alpha = 0.20 \text{ for second threshold}$$

$$s = 5 \text{ seconds sample length}$$

After this thresholding, approximate locations of the R_{peaks} were obtained from the y_m . These points were later mapped on the denoised original signal. Maximum amplitude of the denoised original signal within a particular time window is identified as the final position of the R_{peak} . This window ranges 0.8s along either sides of the approximate location obtained after the thresholding. Maximum values detected too close (distance < average RR interval) to an already identified R_{peak} , it is discarded.

Reconstructed denoised signal (y_m) with information from selected frequency range ($cD_3 - cD_5$) is used to obtain Q_{peak} , QRS_{On} and QRS_{Off} . Minimum value within 0.1s before a detected R_{peaks} is identified as Q_{peak} of that QRS complex. In case of a negative R_{peak} ,

maximum value is considered as the Q_{peak} . First zero crossing in a 0.1s window before the Q_{peak} is identified as QRS_{On} . If a zero crossing is not obtained in that 0.1s frame, a 0.03s window is scanned along this region to find the minimum value. This minimum value is considered as QRS_{On} .

To obtain QRS_{Off} , a different thresholding method (equation 10.2.2) is implemented. The minimum value within 0.1s window before the R_{peaks} is treated as QRS_{min} . If the amplitude of this point is greater than the threshold, algorithm uses y_m for QRS_{Off} detection. Otherwise, only level 3 coefficient's (cD_3 of denoised signal) reconstructed signal component is used to identify QRS_{Off} and S peak.

Threshold,

$$\text{thresh}_{\text{qrs}} = 0.4 \times R(i)$$

(10.2.2)

Where,

R = The amplitude of the current R_{peak}

The minimum value within 0.1s window after R_{peak} corresponds to QRS_{min} . This is an approximate position of S_{peak} . Location of the maximum value within 0.1s after QRS_{min} on the reconstructed denoised signal is the position of QRS_{Off} . Similar to the QRS_{On} detection algorithm, zero crossing after S_{peak} is observed as QRS_{Off} . If zero crossing is not present, nearest local minimum is observed as QRS_{Off} .

9.3. P-wave detection

Signal components of P-wave is present in the following reconstructed signal.

$$y = \begin{cases} D4 + D5 + D6, & P_{\text{peak}} \\ D5 + D6, & P_{\text{on}} \text{ and } P_{\text{off}} \end{cases} \quad (10.3.1)$$

Where,

y = reconstructed signal

D3-D5 = Inverse DWT of detail coefficients cD_3 - cD_5 , respectively

An adaptive searching window SW_p is applied on the original denoised signal. If the local maximum in this range is greater than $thresh_p$, the local maxima within SW_p window in 'y' is identified as the approximate location of the P_{peak} . Otherwise, this peak is considered as P_{peak} .

$$SW_p = [QRS_{on} - 0.33 \times RR_{av} : QRS_{on} - 5] \quad (10.3.2)$$

Where,

RR_{av} = The average of the last 20 RR intervals, in samples

$$thresh_p = 0.125 \times \max(|y_{D4+D5}[n]|) \quad (10.3.3)$$

Where,

n = a window starting 20 samples before the R_{peak} and ending 40 samples after it

If the local maxima on the original denoised signal lies within 25 samples of this identified approximate P_{peak} position from the signal 'y', that point is identified as the final position of P_{peak} . Otherwise, next largest peak is selected as P_{peak} .

The nearest local minimum before the P_{peak} is identified as P_{On} and the nearest local minimum after P_{peak} is identified P_{Off} .

9.4. T-wave detection

Frequency components with information on T-wave are cD_4 , cD_5 and cD_6 . These signal components are added together and reconstructed (y). An adaptive windowing SW_T (in equation 10.4.1) between QRS_{Off} and subsequent QRS_{On} is applied on this reconstructed denoised signal (y) to obtain T_{peak} .

Threshold,

$$SW_T = [QRS_{off} + f_s \times 0.1 : QRS_{on} + 0.65 \times \sqrt{RR_{av}}] \quad (10.4.1)$$

Where,

RR_{av} = The average of the last 20 RR intervals, in samples

Local maxima of the absolute value of 'y' within SW_T is identified and this is compared to the local maxima of the absolute value of denoised original signal within SW_T . Location of T_{peak} 's approximate location is verified using this method. If the largest peak in the original denoised signal lies within 25 samples from the peak in 'y', it is identified as T_{peak} . If the largest peak is not within the range, next large peak is selected. T_{end} is identified as the nearest local minimum in 'y' for positive T_{peak} and nearest local maximum for negative T_{peak} .
